

Recommended Assessment

Visual Servoing

Image Processing

1. Why is the inverse Jacobian matrix used in visual servoing? How does it help control the manipulator's movement?
2. What differences do you observe when switching from 2-joint tracking to all-joint tracking? Why does this change the manipulator's behavior?
3. What limitations might you encounter when tracking objects with different colors or lighting conditions? How could you improve the system's robustness?
4. If the object moves too quickly or leaves the camera frame, how might the system respond?
